Determinantal Expression and Recursion for Jack Polynomials

L. Lapointe†, A. Lascoux††, and J. Morse††

Abstract. We give matrices of which their determinants are the Jack polynomials expanded in terms of the monomial basis. The top row of this matrix is a list of monomial functions, the entries of the sub-diagonal are of the form $-(rα + s)$, with $r$ and $s ∈ N^+$, the entries above the sub-diagonal are non-negative integers, and below all entries are 0. The quasi-triangular nature of this matrix gives a recursion for the Jack polynomials allowing for efficient computation. A specialization of these results yields a determinantal formula for the Schur functions and a recursion for the Kostka numbers.

1. Introduction

The Jack polynomials $J_α[x_1, \ldots, x_N; α]$ form a basis for the space of $N$-variable symmetric polynomials. Here we give a matrix of which the determinant is $J_α[x; α]$ expanded in terms of the monomial basis. The top row of this matrix is a list of monomial functions, the entries of the sub-diagonal are of the form $-(rα + s)$, with $r$ and $s ∈ N^+$, the entries above the sub-diagonal are non-negative integers, and below all entries are 0. The quasi-triangular nature of this matrix gives a simple recursion for the Jack polynomials allowing for their rapid computation. The result here is a transformed specialization of the matrix expressing Macdonald polynomials given in [?]. However, we give a self-contained derivation of the matrix for Jack polynomials. Since the Schur functions $s_λ[x]$ are the specialization $α = 1$ in $J_λ[x; α]$, we obtain a matrix of which the determinant gives $s_λ[x]$. A by-product of this result is a recursion for the Kostka numbers, the expansion coefficients of the Schur functions in terms of the monomial basis.

Partitions are weakly decreasing sequences of non-negative integers. We use the dominance order on partitions, defined $μ ≤ λ ⇐⇒ μ_1 + \cdots + μ_i ≤ λ_1 + \cdots + λ_i \forall i$. The number of non-zero parts of a partition $λ$ is denoted $ℓ(λ)$. The Jack polynomials can be defined up to normalization by the conditions

\begin{align*}
(i) \quad J_λ &= \sum_{μ ≤ λ} v_{λμ} m_μ, \quad \text{with} \quad v_{λλ} \neq 0, \\
(ii) \quad HJ_λ &= \sum_{i=1}^{N} \left( \frac{α}{2} λ_i^2 + \frac{1}{2} (N + 1 - 2i)λ_i \right) J_λ, \quad (1)
\end{align*}

where $H$ is the Hamiltonian of the Calogero-Sutherland model [?] defined

\begin{equation}
H = \frac{α}{2} \sum_{i=1}^{N} x_i \frac{∂}{∂x_i} + \frac{1}{2} \sum_{i<j} \left( x_i + x_j \right) \left( x_i \frac{∂}{∂x_i} - x_j \frac{∂}{∂x_j} \right). \quad (2)
\end{equation}

A composition $β = (β_1, \ldots, β_n)$ is a vector of non-negative integral components and the partition rearrangement of $β$ is denoted $β^*$. The raising operator $R_{ij}^β$ acts...
on compositions by $R_{ij}^k \beta = (\beta_1, \ldots, \beta_i - \ell, \ldots, \beta_j + \ell, \ldots, \beta_n)$, for any $i < j$. We will use $n(k)$ to denote the number of occurrences of $k$ in $\mu$. This given, we use the following theorem [?]

**Theorem 1.** Given a partition $\lambda$, we have

$$H m_\lambda = \sum_{i=1}^{\ell(\lambda)} \left( \frac{\alpha}{2} \lambda_i^2 + \frac{1}{2}(N + 1 - 2i)\lambda_i \right) m_\lambda + \sum_{\mu < \lambda} C_{\lambda \mu} m_\mu ,$$

where if there exists some $i < j$, and $1 \leq \ell \leq \left\lfloor \frac{\lambda_i - \lambda_j}{2} \right\rfloor$ such that $(R_{ij}^\ell \lambda)^\ast = \mu$, then

$$C_{\lambda \mu} = \begin{cases} (\lambda_i - \lambda_j)\binom{n(\mu)}{2} & \text{if } \mu_i = \mu_j \\ (\lambda_i - \lambda_j)n(\mu_i)n(\mu_j) & \text{if } \mu_i \neq \mu_j \end{cases}$$

and otherwise $C_{\lambda \mu} = 0$.

**Example 1:** with $N = 5$,

- $H m_4 = (8 + 8\alpha)m_4 + 4m_{3,1} + 4m_{2,2}$
- $H m_{2,1,1} = (5 + 3\alpha)m_{2,1,1} + 12m_{1,1,1,1}$
- $H m_{3,1} = (7 + 5\alpha)m_{3,1} + 2m_{2,2} + 6m_{2,1,1}$
- $H m_{1,1,1,1} = (2 + 2\alpha)m_{1,1,1,1}$
- $H m_{2,2} = (6 + 4\alpha)m_{2,2} + 2m_{2,1,1}$

2. **Determinant for the Jack Polynomials**

We can obtain non-vanishing determinants which are eigenfunctions of the Hamiltonian $H$ by using the triangular action of $H$ on the monomial basis.

**Theorem 2.** If $\mu^{(1)}, \mu^{(2)}, \ldots, \mu^{(n)} = \mu$ is a linear ordering of all partitions $\leq \mu$, then the Jack polynomial $J_{\mu}$ is proportional to the following determinant;

$$J_\mu \doteq \begin{vmatrix} m_{\mu^{(1)}} & m_{\mu^{(2)}} & \cdots & \cdots & m_{\mu^{(n-1)}} & m_{\mu^{(n)}} \\ d_{\mu^{(1)}} - d_{\mu^{(n)}} & C_{\mu^{(2)}\mu^{(1)}} & \cdots & \cdots & C_{\mu^{(n-1)}\mu^{(1)}} & C_{\mu^{(n)}\mu^{(1)}} \\ 0 & d_{\mu^{(2)}} - d_{\mu^{(n)}} & \cdots & \cdots & C_{\mu^{(n-1)}\mu^{(2)}} & C_{\mu^{(n)}\mu^{(2)}} \\ \vdots & 0 & \ddots & \ddots & \vdots & \vdots \\ \vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & d_{\mu^{(n-1)}} - d_{\mu^{(n)}} & C_{\mu^{(n)}\mu^{(n-1)}} \end{vmatrix}$$

where $d_\lambda$ denotes the eigenvalue in 1(ii) and $C_{\mu^{(i)}\mu^{(j)}}$ is defined by (4).

Note that in the case $\mu = (a)$, the matrix $J_a$ contains all possible $C_{\mu^{(i)}\mu^{(j)}}$. Therefore, the matrices corresponding to $J_1, J_2, \ldots$ determine the entries off the sub-diagonal for all other matrices. Further, the sub-diagonal entries $d_{\mu^{(i)}} - d_{\mu^{(n)}}$ do not depend on the number of variables $N$, when $N \geq \ell(\mu)$, since for any partitions $\mu$ and $\lambda$ where $\ell(\mu) \geq \ell(\lambda)$,

$$d_\mu - d_\lambda = \sum_{i=1}^{\ell(\mu)} \left( \frac{\alpha}{2} (\mu_i^2 - \lambda_i^2) - i(\mu_i - \lambda_i) \right).$$

It is also easily checked that if $\mu < \lambda$, then $d_\mu - d_\lambda = -(r + sa)$ for some $r, s \in \mathbb{N}^+$, showing that the sub-diagonal entries are of this form.
Example 2: The entries of the matrix for $J_4$ are obtained using the action of $H$ on $m_{\mu^{(i)}}$, where $\mu^{(1)} = (1, 1, 1, 1)$, $\mu^{(2)} = (2, 1, 1, 1)$, $\mu^{(3)} = (2, 2, 2)$, $\mu^{(4)} = (3, 1, 1)$, $\mu^{(5)} = (4)$, given in Example 1:

$$J_4 = \begin{vmatrix}
m_{1,1,1,1} & m_{2,1,1} & m_{2,2} & m_{3,1} & m_4 \\
-6 - 6\alpha & 12 & 0 & 0 & 0 \\
0 & -3 - 5\alpha & 2 & 6 & 0 \\
0 & 0 & -2 - 4\alpha & 2 & 4 \\
0 & 0 & 0 & -1 - 3\alpha & 4
\end{vmatrix} \quad (7)$$

We also obtain a determinantal expression for the Schur functions in terms of monomials using Theorem 2 since $s_\lambda[x]$ is the specialization $J_\lambda[x; 1]$.

Corollary 3. Given a partition $\mu$, the specialization $\alpha = 1$ in the determinant (5) is proportional to the Schur function $s_\mu$.

Example 3: $s_4$ can be obtained by specializing $\alpha = 1$ in the matrix (7).

$$s_4 = \begin{vmatrix}
m_{1,1,1,1} & m_{2,1,1} & m_{2,2} & m_{3,1} & m_4 \\
-12 & 12 & 0 & 0 & 0 \\
0 & -8 & 2 & 6 & 0 \\
0 & 0 & -6 & 2 & 4 \\
0 & 0 & 0 & -4 & 4
\end{vmatrix} \quad (8)$$

Proof of Theorem 2. We have from (6) that $d_\lambda \neq d_\mu$ for $\lambda < \mu$ implying that the sub-diagonal entries, $d_{\mu^{(i)}} - d_\mu$, of determinantal expression (5) are non-zero. Since the coefficient of $m_{\mu^{(n)}} = m_\mu$ is the product of the sub-diagonal elements, this coefficient does not vanish and by the construction of $J_\mu$, Property 1(i) is satisfied.

It thus suffices to check that $(H - d_\mu) J_\mu = 0$. Since $H$ acts non-trivially only on the first row of the determinant $J_\mu$, the first row of $(H - d_\mu) J_\mu$ is obtained from Theorem 1 and expression (5) gives rows 2, ..., $n$.

$$(H - d_\mu) J_\mu = \begin{vmatrix}
\vdots & d_{\mu^{(i)}} m_{\mu^{(i)}} + \sum_{i<j} C_{\mu^{(i)}\mu^{(j)}} m_{\mu^{(j)}} - d_\mu m_{\mu^{(j)}} & \vdots \\
\vdots & C_{\mu^{(i)}\mu^{(j)}} & \vdots \\
\vdots & C_{\mu^{(i)}\mu^{(j-1)}} & \vdots \\
\vdots & d_{\mu^{(j)}} - d_\mu & \vdots \\
\vdots & 0 & \vdots \\
\vdots & & \vdots
\end{vmatrix}$$

$m_{\mu^{(n)}}$ appears only in the first row, column $n$, with coefficient $d_\mu - d_\mu = 0$. Further, we have that the first row is the linear combination: $m_{\mu^{(1)}} row_2 + m_{\mu^{(2)}} row_3 + \cdots + m_{\mu^{(n-1)}} row_n$, and thus the determinant must vanish.
3. Recursion for quasi-triangular matrices

We use the determinantal expressions for Jack and Schur polynomials to obtain recursive formulas. First we will give a recursion for $J_\lambda[x; \alpha]$ providing an efficient method for computing the Jack polynomials and we will finish our note by giving a recursive definition for the Kostka numbers. These results follow from a general property of quasi-triangular determinants [7, 8]:

**Property 4.** Any quasi-triangular determinant of the form

\[
D = \begin{vmatrix}
  b_1 & b_2 & \cdots & b_{n-1} & b_n \\
  -a_{21} & a_{22} & \cdots & a_{2,n-1} & a_{2,n} \\
  0 & -a_{32} & \cdots & a_{3,n-1} & a_{3,n} \\
  \vdots & \ddots & \ddots & \vdots & \vdots \\
  0 & 0 & 0 & -a_{n,n-1} & a_{n,n}
\end{vmatrix} 
\]  

has the expansion $D = \sum_{i=1}^{n} c_i b_i$, where $c_n = a_{21} a_{32} \cdots a_{n,n-1}$ and

\[
c_i = \frac{1}{a_{i+1,i}} \sum_{j=i+1}^{n} a_{i+1,j} c_j \quad \text{for all } i \in \{1, 2, \ldots, n-1\}.
\]  

**Proof.** Given linearly independent $n$-vectors $b$ and $a^{(i)}$, $i \in \{2, \ldots, n\}$, let $c$ be a vector orthogonal to $a^{(2)}, \ldots, a^{(n)}$. This implies that the determinant of a matrix with row vectors $b, a^{(2)}, \ldots, a^{(n)}$ is the scalar product $(c, b) = \sum_{i=1}^{n} c_i b_i$, up to a normalization. In the particular case of matrices with the form given in (9), that is with $a^{(i)} = (0, \ldots, 0, -a_{i,i-1}, a_{i,i}, \ldots, a_{i,n})$, $i \in \{2, \ldots, n\}$, we can see that $(c, a^{(i)}) = 0$ if the components of $c$ satisfy recursion (10). Since we have immediately that the coefficient of $b_n$ in (9) is $c_n = a_{21} \cdots a_{n,n-1}$, ensuring that $\sum_{i=1}^{n} c_i b_i$ is properly normalized, Property 4 is thus proven.

Notice that we can freely multiply the rows of matrix (9) by non-zero constants and still preserve recursion (10). This implies that to obtain a matrix proportional to determinant (9), one would simply multiply the value of $c_n$ by the proportionality constant.

Since the determinantal expression (5) for the Jack polynomials is of the form that appears in Property 4, we may compute the Jack polynomials, in any normalization, using recursion (10).

**Example:** Recall that $v_{(4);(4)} = (1 + \alpha)(1 + 2\alpha)(1 + 3\alpha)$ in the normalization associated to the positivity of Jack polynomials [7, 8, 9]. Thus, using

\[
J_4 = \begin{vmatrix}
  m_{1,1,1,1} & m_{2,1,1} & m_{2,2} & m_{3,1} & m_4 \\
  -6 - 6\alpha & 12 & 0 & 0 & 0 \\
  0 & -3 - 5\alpha & 2 & 6 & 0 \\
  0 & 0 & -2 - 4\alpha & 2 & 4 \\
  0 & 0 & 0 & -1 - 3\alpha & 4
\end{vmatrix},
\]  

and initial condition $c_5 = (1 + \alpha)(1 + 2\alpha)(1 + 3\alpha)$, we get

\[
c_4 = \frac{1}{1 + 3\alpha}(4c_5) = 4(1 + \alpha)(1 + 2\alpha), \quad c_2 = \frac{1}{3 + 5\alpha}(2c_3 + 6c_4) = 12(1 + \alpha), \\
\]

\[
c_3 = \frac{1}{2 + 4\alpha}(2c_4 + 4c_5) = 6(1 + \alpha)^2, \quad c_1 = \frac{1}{6 + 6\alpha}(12c_2) = 24.
\]
which gives that
\[ J_4 = (1 + \alpha)(1 + 2\alpha)(1 + 3\alpha)m_4 + 4(1 + \alpha)(1 + 2\alpha)m_{3,1} \]
\[ + 6(1 + \alpha)^2 m_{2,2} + 12(1 + \alpha)m_{2,1,1} + 24m_{1,1,1,1}. \]  (13)

If we let \( \mu^{(1)}, \mu^{(2)}, \ldots, \mu^{(n)} = \mu \) be a linear ordering of all partitions \( \leq \mu \) and recall that the Kostka numbers are the coefficients \( K_{\mu\mu^{(i)}} \) in
\[ s_{\mu}[x] = \sum_{i=1}^{n} K_{\mu\mu^{(i)}} m^{(i)}[x] \text{ where } K_{\mu\mu^{(n)}} = K_{\mu\mu} = 1, \]  (14)
we can use Property 4 to obtain a recursion for the \( K_{\mu\mu^{(i)}} \).

**Corollary 5.** Let \( \mu^{(1)}, \mu^{(2)}, \ldots, \mu^{(n)} = \mu \) be a linear ordering of all partitions \( \leq \mu \). \( K_{\mu\mu^{(i)}} \) is defined recursively, with initial condition \( K_{\mu\mu} = 1 \), by
\[ K_{\mu\mu^{(i)}} = \frac{1}{g_{\mu^{(i)}} - g_{\mu}} \sum_{j=i+1}^{n} C_{\mu^{(i+1)}\mu^{(j)}} K_{\mu\mu^{(j)}} \text{ for all } i \in \{1, 2, \ldots, n-1\}, \]  (15)
where \( C_{\mu^{(i+1)}\mu^{(j)}} \) is given in (4) and where \( g_{\mu^{(i)}} - g_{\mu} \) is the specialization \( \alpha = 1 \) of \( d_{\mu^{(i)}} - d_{\mu} \) introduced in (4).
