

## First isomorphism theorem, and symmetries of a cube

In this lecture we prove the “1st Isomorphism Theorem” and discuss some consequences. We also explore the rotational symmetries of a cube in 3-dimensional Euclidean space.

► **1st Isomorphism Theorem:** Let  $\phi : G \rightarrow G'$  be an *onto* homomorphism. Then there is a naturally induced map which we write as

$$\psi : G/\ker(\phi) \longrightarrow G'$$

and this map  $\psi$  is an isomorphism of groups.

*Proof.* Write  $N = \ker(\phi)$ . Define the map  $\psi$  as follows: for any coset  $aN \in G/N$  we let  $\psi(aN) = \phi(a)$ . Let us check this is well-defined. Suppose  $aN = bN$ . This means  $ab^{-1} \in N$ , i.e.  $e' = \phi(ab^{-1}) = \phi(a)\phi(b)^{-1}$ . Thus  $\phi(a) = \phi(b)$ . In particular,

$$\phi(a) = \psi(aN) = \psi(bN) = \phi(b)$$

This tells us  $\psi$  is well-defined map, independent of how the coset  $aN$  is written.

Next, we check  $\psi$  is a homomorphism. For  $aN, bN \in G/N$  we simply compute

$$\psi(aN)\psi(bN) = \phi(a)\phi(b) = \phi(ab) = \psi(abN) = \psi(aNbN)$$

and thus  $\psi$  is a homomorphism.

Finally, we check that  $\psi$  is 1-1 and onto. Let  $a' \in G'$ . Because  $\phi$  is onto, there is some  $a \in G$  such that  $\phi(a) = a'$ . Then also  $\psi(aN) = \phi(a) = a'$ . Therefore  $\psi$  is onto. Finally, suppose  $aN, bN \in G/N$  are such that  $\psi(aN) = \psi(bN)$ . This implies  $\phi(a) = \phi(b)$ , or  $\phi(ab^{-1}) = e'$ , implying  $ab^{-1} \in N$ . In particular,  $aN = bN$ . Thus  $\psi$  is 1-1, and  $\psi$  is an isomorphism.  $\square$

### Examples

1. Let  $\phi : \mathbb{Z}_{20} \rightarrow \mathbb{Z}_5$  be the homomorphism given by  $\phi(k \pmod{20}) = k \pmod{5}$ . Then  $\ker(\phi) = \langle 5 \rangle \subset \mathbb{Z}_{20}$ . The 1st Isomorphism Theorem gives

$$\mathbb{Z}_{20}/\langle 5 \rangle \cong \mathbb{Z}_5$$

2. Consider the exponential map  $\phi : (\mathbb{R}, +) \rightarrow (U(1), \times)$ , where  $U(1) \subset \mathbb{C}^\times$  is the circle group, defined by  $\phi(\theta) = e^{2\pi i\theta}$ . This is an onto homomorphism. The kernel is

$$\ker(\phi) = \{\theta \in \mathbb{R} : e^{2\pi i\theta} = 1\} = \mathbb{Z} \subset \mathbb{R}$$

By the 1st isomorphism theorem we conclude we have an isomorphism

$$\mathbb{R}/\mathbb{Z} \cong U(1)$$

3. Consider the group of upper triangular matrices in  $\text{GL}_2(\mathbb{R})$  given by

$$G = \left\{ A = \begin{pmatrix} a & b \\ 0 & c \end{pmatrix} : a, b, c \in \mathbb{R}, ac \neq 0 \right\}$$

Define a map  $\phi : G \rightarrow \mathbb{R}^\times \times \mathbb{R}^\times$  by  $\phi(A) = (a, c)$ . This is easily checked to be an onto homomorphism. The kernel of  $\phi$  is given by the subgroup  $H \subset G$  of upper triangular matrices with  $a = c = 1$ . Thus  $H$  is normal. The 1st Isomorphism Theorem gives

$$G/H \cong \mathbb{R}^\times \times \mathbb{R}^\times$$

In particular,  $G/H$  is abelian.

► **Let  $G$  be cyclic. If  $|G| = \infty$  then  $G \cong \mathbb{Z}$ . If  $|G|$  is finite then  $G \cong \mathbb{Z}_n$  where  $n = |G|$ .**

*Proof.* Since  $G$  is cyclic,  $G = \langle a \rangle = \{a^k : k \in \mathbb{Z}\}$  for some  $a \in G$ . Define a map

$$\phi : \mathbb{Z} \longrightarrow G$$

by setting  $\phi(k) = a^k$ . Then this is onto, since  $a$  generates  $G$ . The kernel of  $\phi$  consists of  $m \in \mathbb{Z}$  such that  $a^m = e$  in  $G$ . There are two cases. If  $G$  is finite, then  $|G| = n$  is the order of  $a$  and  $\ker(\phi) = n\mathbb{Z} \subset \mathbb{Z}$ . The 1st Isomorphism Theorem gives

$$\mathbb{Z}_n = \mathbb{Z}/n\mathbb{Z} = \mathbb{Z}/\ker(\phi) \cong G$$

In the other case,  $G$  is infinite, and there are no  $m$  aside from  $m = 0$  such that  $a^m = e$ , and thus the kernel of  $\phi$  is trivial. Then  $G \cong \mathbb{Z}$ .  $\square$

## Symmetries of a cube

Now let us turn to the group  $G$  which consists of the rotational symmetries of a cube situated in 3-dimensional Euclidean space. This group has 24 elements, as shown on the next page. We first follow a familiar strategy of describing this group: label the vertices 1 to 8, and associate to each rotation  $a \in G$  a corresponding permutation  $\phi(a) \in S_8$  based on how the vertices are moved around. This gives a homomorphism

$$\phi : G \longrightarrow S_8$$

This homomorphism  $\phi$  is 1-1, but it is not onto: indeed,  $|G| = 24$  but the target group  $S_8$  has  $8! = 40320$  elements.

Mapping  $G$  into  $S_8$  is not the most ideal scenario. After all,  $|S_8| = 40320$  whereas  $G$  has order only 24. A better way of representing  $G$  as a group of permutations is as follows.

There are 4 diagonal axes that pass through the cube; each one goes through two vertices that are as far apart as possible. Label these 4 diagonal axes 1, 2, 3, 4. Then for a rotation  $a \in G$  we define  $\psi(a) \in S_4$  to be the permutation determined by how the diagonal axes are moved around by the rotation  $a$ . This gives a homomorphism

$$\psi : G \longrightarrow S_4$$

It is straightforward to verify that  $\psi$  is 1-1, i.e. that a rotation of the cube is entirely determined by how these 4 diagonal axes are permuted. Then, since  $|G| = 24 = |S_4|$ , we know  $\psi$  must also be onto. Therefore  $\psi$  is an isomorphism! The construction of the map  $\psi$  is illustrated on the next page.

Finally, let us return to the 1st Isomorphism Theorem. To this end, we define a map

$$\mu : S_4 \longrightarrow S_3$$

as follows. Let  $\sigma \in S_4$ . Then  $a = \psi^{-1}(\sigma) \in G$  is a rotational symmetry of the cube. Consider the six pictures of the cube below, each with a distinguished pair of diagonal axes chosen. These six pictures of the cube are divided into 3 columns labelled 1, 2, 3.

You may verify that the rotation  $a$  takes the two pictures in column 1 to either the two pictures in column 2, or the two pictures in column 3, and so on. Thus the columns 1, 2, 3 above are permuted. We obtain a permutation of  $\{1, 2, 3\}$  which we call  $\mu(\sigma) \in S_3$ . Further,

$$\ker(\mu) = H = \{e, (12)(34), (13)(24), (14)(23)\},$$

is a normal subgroup, and  $\mu$  is onto. The 1st Isomorphism Theorem then tells us that

$$S_4/H \cong S_3$$

This example is actually rare: there are no homomorphisms  $S_n \rightarrow S_{n-1}$  when  $n > 4$ !

# Rotational symmetries of a cube

Original position  
with vertices labelled 1-8

There are 24 symmetries.

By keeping track of where vertices go, we get a 1-1 homomorphism

$$\left\{ \begin{array}{l} \text{rotational symmetries} \\ \text{of the cube} \end{array} \right\} \longrightarrow S_8.$$

identity: corresponds to identity permutation  $e \in S_8$

For each axis as below, get 3 nontrivial rotations:

$90^\circ$  (2358)(1467)  
 $180^\circ$  (25)(38)(16)(47)  
 $270^\circ$  (2853)(1764)

$90^\circ$  (1234)(5678)  
 $180^\circ$  (13)(24)(57)(68)  
 $270^\circ$  (1432)(5876)

$90^\circ$  (1287)(5643)  
 $180^\circ$  (18)(27)(54)(63)  
 $270^\circ$  (1782)(5346)

2 nontrivial rotations around each of the 4 diagonal axes:

$120^\circ$  (386)(274)  
 $240^\circ$  (368)(247)

$120^\circ$  (183)(475)  
 $240^\circ$  (138)(457)

$120^\circ$  (168)(245)  
 $240^\circ$  (186)(254)

$120^\circ$  (257)(136)  
 $240^\circ$  (275)(163)

$180^\circ$  rotation around each edge-midpoint diagonal:

(17)(26)(35)(48)

(15)(28)(37)(46)

(15)(26)(34)(78)

(12)(37)(48)(56)

(14)(26)(37)(58)

(15)(23)(48)(67)
